TERMINOLOGY

- MVC Model-View-Controller is the "keep stuff separate" philosophy to separate out the code in a complicated web apps into 3 different categories
- **ORM** Object Relational Mapper the type of library that lets us create special classes (called *models*) that can be saved and retrieved from the database (e.g. SQLite). Writes SQL code, so we don't have to.
- migration Auto-generated code that uses the ORM to get the database sync'ed up with the latest additions to a project's models.
- applying migration Using a migration to get the DB upto-date and ready for use.
- MVT Model-View-Template are the three categories of code in a Django project
- **app** A single Django-powered *project* can be split up into multiple apps. Each app can have a full vertical "slice" of models, views, and templates.

Models, Views, and Forms

models.py - Define a "Person" as having a name and email

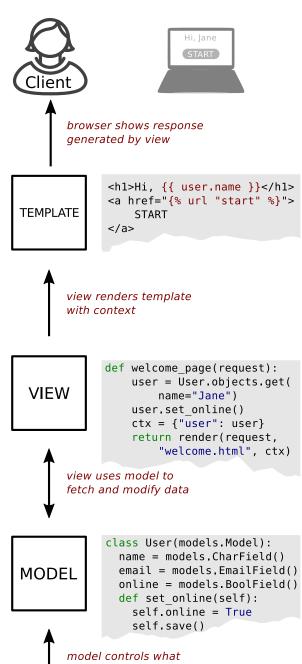

```
class Person(models.Model):
   name = forms.CharField(max_length=64)
   email = forms.EmailField()
```

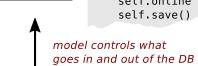

views.py - Example code for using a form and a model to gather and validate user input.

```
class NewPersonForm(forms.Form):
   name = forms.CharField(required=True)
    email = forms.EmailField()
# urls.py has: path("create/", views.person_create),
def person_create(request):
    if request.method == "GET":
        # Is initial GET: Create a blank form
        form = NewPersonForm()
    else:
        # Is POST: Create a form based on POST data
        form = NewPersonForm(request.POST)
        if form.is_valid():
            # If valid, create a new person & redirect
            person = Person()
            person.username = form.cleaned_data["name"]
            person.email = form.cleaned_data["email"]
            person.save()
            return redirect("/thanks/")
    ctx = {"form": form}
    return render(request, "create.html", ctx)
```

templates/create.html

```
<h1>Create new user</h1>
<form action="." method="post">
    {% csrf_token %}
    {{ form }}
    <button>Submit</button>
</form>
```

CREATE TABLE `users`			
id	name	email	online
13 14	Jane alice	j@do.com alice@	1 0

model is the gate-keeper to data stored in the *database* **view** defines business logic of your web app template is the appearance of your site in HTML
